Questio	on 2	(15 min)	
Q2.1	Alice clears all her network settings and broadcasts a DHCP discover message. What information should she expect to receive in the DHCP offer in response?		
	☐ (A) DNS server	☐ (D) Premaster secret	
	☐ (B) Source port	☐ (E) Gateway router	
	☐ (C) Lease time	☐ (F) IP address	
Q2.2	After receiving the DHCP offer, Alice tries connecting to www.cutecats.com, but instead of pictures of cats, the site she gets is filled with dog photos. How did the attacker compromise DHCP to accomplish this?		
	Which of the following could the attacker have replaced?		
	☐ (G) DNS server	☐ (J) Premaster secret	
	☐ (H) Source port	☐ (K) Gateway router	
	☐ (I) Lease time	☐ (L) IP address	

Q2.3	with TCP. Now an off-path attacker wants to send a packet to the server to interpret Alice's connection. What information do they need to know?			
	\square (A) Server sequence number	☐ (D) Destination IP address		
	☐ (B) Source port	☐ (E) Destination port		
	\square (C) Client sequence number	☐ (F) Source IP address		
Q2.4		ww.cutecats.com is suddenly terminated. the attacker correctly guessed the fields from the to execute this attack?		
	$\bigcirc \ (G) \qquad \bigcirc \ (H) \qquad \bigcirc \ (I)$	$\bigcirc (J) \bigcirc (K) \bigcirc (L)$		

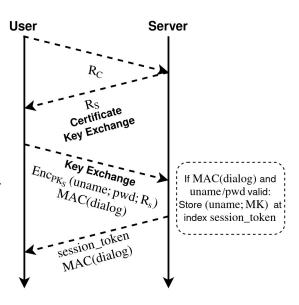

Question 3 (37 min)

FastCash is a fast banking service which requires users to log in before making a transfer, and uses TLS with ephemeral Diffie Hellman and RSA certificates to secure all their connections. They implemented a TLS extension called *0-Round Trip* (*0-RTT*) to speed up the connection process. 0-RTT changes the initial handshake as follows:

- Users authenticate themselves during the second round of the handshake
- If the user authenticates correctly, the server stores a session_token for that user

(Recall that in TLS, PS, R_S , and R_C generate a master key set MK which contains all the symmetric keys. Enc_{PK_S} denotes RSA encryption using the server's public RSA key.)

A user only needs to perform the modified TLS handshake once. To send an HTTP request after the initial connection ends, a user encrypts it using the keys derived in the initial handshake and attaches the session_token. The server verifies that the entry session_token: (uname, MK) exists and, if so,

decrypts and executes the request as the user Simplified diagram of modified initial TLS handshake uname using the keys derived from MK.

Assume that any on-path TCP injection attacks are impossible, and that once a user makes the initial modified TLS handshake, they will use the 0-RTT extension for future requests to the server.

- Q3.1 An on-path attacker observes an initial TLS handshake between a user and server, as well as a subsequent 0-RTT packet which contains an encrypted HTTP request. What can they do?
 - \square (A) Read the user's future communications
 - \square (B) Pretend to be the server to the user
 - \square (C) Pretend to be the user to the server in a new handshake
 - ☐ (D) Replay the encrypted HTTP request to the server
 - \square (E) Learn the master key set
 - \square (F) None of the above

Q3.2	Suppose we removed R_S from the user's KeyExchange in the third step of the handshake. After observing an initial handshake between a user and the server, what can an on-path adversary do?
	\square (G) Read the user's future communications
	\square (H) Pretend to be the server to the user
	\square (I) Pretend to be the user to the server in a new handshake
	\square (J) Learn the premaster secret
	☐ (K) Learn the master key set
	☐ (L) None of the above
Q3.3	Due to a bug, an on-path adversary is able to choose the server's R_S . After observing an initial handshake between a user and the server, what can they do?
	\square (A) Read the user's future communications
	\square (B) Pretend to be the server to the user
	\square (C) Pretend to be the user to the server in a new handshake
	\square (D) Learn the premaster secret
	☐ (E) Learn the master key set
	\square (F) None of the above
Q3.4	An on-path adversary observes a user and the server communicating using 0-RTT for some time (without observing the initial handshake). At some point in the future, the adversary manages to learn all of the server's session_token: (uname, MK) entries. What can they do?
	\square (G) Read the user's future communications
	\square (H) Pretend to be the server to the user
	\square (I) Pretend to be the user to the server in a new handshake
	\square (J) Learn the premaster secret
	☐ (K) Learn the master key set
	☐ (L) None of the above

Q3.5	Consider a MITM adversary during the initial handshake between a user and the	
	Describe how this adversary can send a malicious HTTP request that appears from the legitimate user (Be specific with what is sent). Disregard any bugs from	
	parts.	previous
